Krabbe Disease, Full Gene Analysis			REPORTED 06/27/2012 15:14		
Specimen		Blood			MCR
Specimen ID		1038319			MCR
Order Date		27 Jun 2012 07:24			MCR
Reason For Referral					MCR

Patient reported to have features suggestive of Krabbe disease. Test for the presence of mutations in the GALC gene.

Method MCR

DNA sequence analysis was used to test for the presence of mutations in all 17 exons of the GALC gene. Additionally, a PCR-based assay is utilized to test for the presence of a 30-kb deletion spanning exon 11 through the end of the GALC gene. Mutation nomenclature is based on GenBank accession number; NM_000153.2.

Result MCR

A mutation was NOT detected.

Interpretation MCR

This result decreases the likelihood but does not rule out the diagnosis of Krabbe disease. We predict that a small percentage of individuals who have a diagnosis of Krabbe disease may have mutations that are not identified by the methods described (e.g. large deletions/duplications, promoter mutations, or deep intronic mutations).

This result should be interpreted in the context of clinical findings, family history, and other laboratory testing (e.g. galactosylceramide beta-galactosidase activity in leukocytes or fibroblasts).

A genetic consultation may be of benefit.

A list of common polymorphisms identified for this patient is available upon request.

CAUTIONS:
Test results should be interpreted in context of clinical findings, family history, and other laboratory data. Misinterpretation of results may occur if the information provided is inaccurate or incomplete.

Rare polymorphisms exist that could lead to false negative or positive results. If results obtained do not match the clinical findings, additional testing should be considered.
