Lyme Disease Ab (Serum and CSF), WB			REPORTED 01/16/2013 12:42		
Lyme Disease Antibodies (Serum), WB					
Lyme IgG (Serum) Interpretation		NEGATIVE			Y038
Lyme IgG (Serum) Bands Detected		93Kd			Y038
Lyme IgM (Serum) Interpretation		NEGATIVE			Y038
Lyme IgM (Serum) Bands Detected		93Kd			Y038
Lyme Disease Antibodies (CSF), WB					
Lyme IgG (CSF) Result		See Below			Y038
Result: ANTIBODY NOT DETECTED					
Lyme IgG (CSF) Bands Detected		93Kd			Y038
Lyme IgM (CSF) Result		See Below			Y038
Result: ANTIBODY NOT DETECTED					
Lyme IgM (CSF) Bands Detected		93Kd			Y038

REFERENCE RANGE FOR SERUM: NEGATIVE
REFERENCE RANGE FOR CSF: ANTIBODY NOT DETECTED

Lyme disease is caused by Borrelia burgdorferi. CDC criteria for a positive Lyme IgG immunoblot for serum require the presence of IgG to at least 5 of 10 specific borrelial proteins (18Kd, 23Kd, 30Kd, 39Kd, 41Kd, 45Kd, 58Kd, 66Kd, 93Kd). CDC criteria for a positive IgM immunoblot for serum require the presence of IgM to at least 2 of 3 specific borrelial proteins (23Kd, 39Kd, 41Kd). The presence of 1 to 4 IgG bands or one IgM band (indeterminate results) may indicate recent exposure to B. burgdorferi and may warrant further serologic testing if clinically indicated. Reactivity to the 41Kd band may be observed in sera from normal individuals, as well as sera containing anti-nuclear antibodies (ANA). In rare instances, reactivity to B. burgdorferi proteins may represent crossreactive antibodies induced by infection with other spirochetes, such as Treponema pallidum.

No interpretive criteria for Lyme immunoblots have been established for CSF. The presence of Lyme IgG and/or IgM in CSF may represent either compartmental antibody production or transudation of plasma antibody. Detection of Lyme antibodies in CSF but not a paired serum sample most likely represents false positive reactivity.
