OPRM1 Interpretation

MCR

Homozygous OPRM1 355A/355A [Asn/Asn]. This individual is homozygous for the OPRM1 355A allele which encodes for the Asparagine/Asparagine genotype. The Asparagine allele has been associated with a poorer response to naltrexone treatment in alcoholics, including an increased risk of relapse.

ADDITIONAL INFORMATION

Direct polymorphism analysis of the OPRM1 355A>G [Asn102Asp] polymorphism is performed by a Polymerase Chain

Reaction (PCR) based 5'-nuclease assay using fluorescently labeled detection probes. Historically the mutation has been referred to as OPRM1 118A>G [Asn40Asp]. This DNA testing will not detect all the known mutations and polymorphisms of OPRM1. Absence of mention of a specific gene mutation or polymorphism does not rule out the possibility that a patient has that or another variation that can impact the function of this receptor, drug response or drug side effects.

CAUTIONS:

If the patient has had an allogeneic blood or marrow transplant or a recent (i.e. less than 6 weeks from time of sample collection) heterologous blood transfusion these results may be inaccurate due to the presence of donor DNA. For research use only.
